

1. Find out the amplitude and the phase angle of the following equations:

$$f(t) = 64 + 26\cos(2 \pi k t / N) + 13 \sin(2 \pi k t / N)$$

If  $N=200$  then what is the frequency for  $k=1$ . Use the above equation to find out the frequency.

**Attached in 1\_2.pdf**

2. What would be the transformed formula,  $F(w)$ , to calculate the frequency of the series?

$$f(t) = -1 \text{ for } 0 < t < a$$

$$f(t) = 0 \text{ elsewhere}$$

**\*\*Either type or use legible handwriting to find the integrated function.**

**Attached in 1\_2.pdf**

3. Construct the entire Fourier series of the “DIS” data using:

K=1 between 0-25

K=2 between 25-140

K=3 between 140-220

K=4 between 220-250

K=5 between 250-310

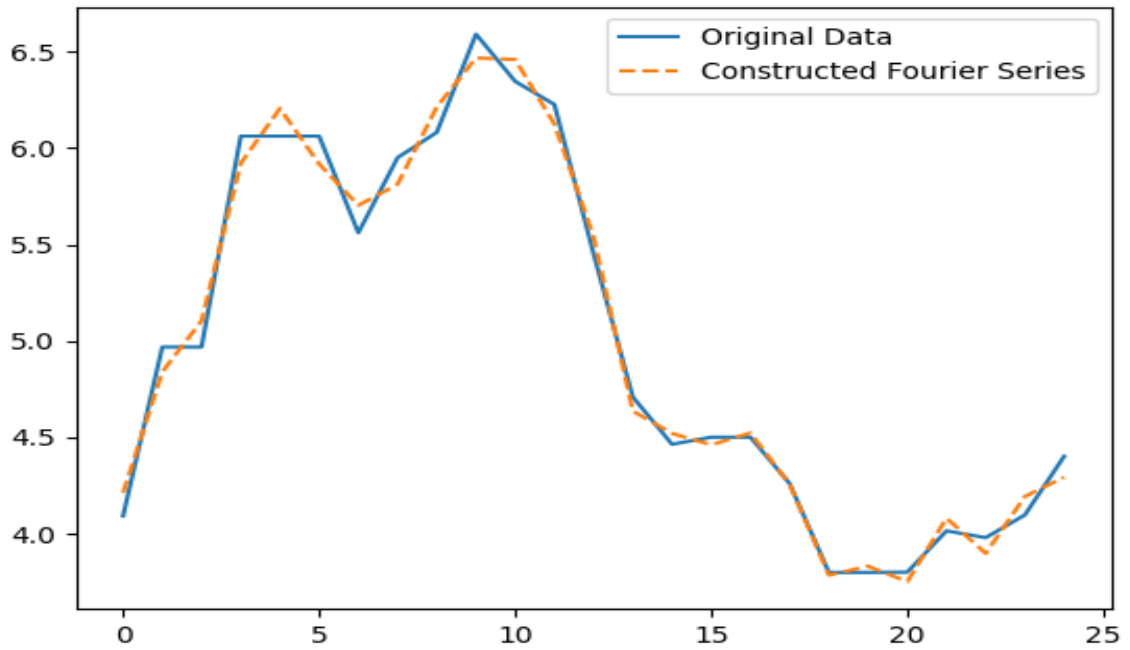

K=6 between 310-350

K=7 between 350-506

Compute the frequencies and amplitudes for each of the individual series. Also, compute the same for the entire time series (0-506). Do you see any differences?

The time series (0-506) exhibits a greater variety of amplitudes and frequencies in comparison to others. The corresponding codes and outputs can be found in the attached `fourier_series.ipynb` file. I have attached the outputs below also.

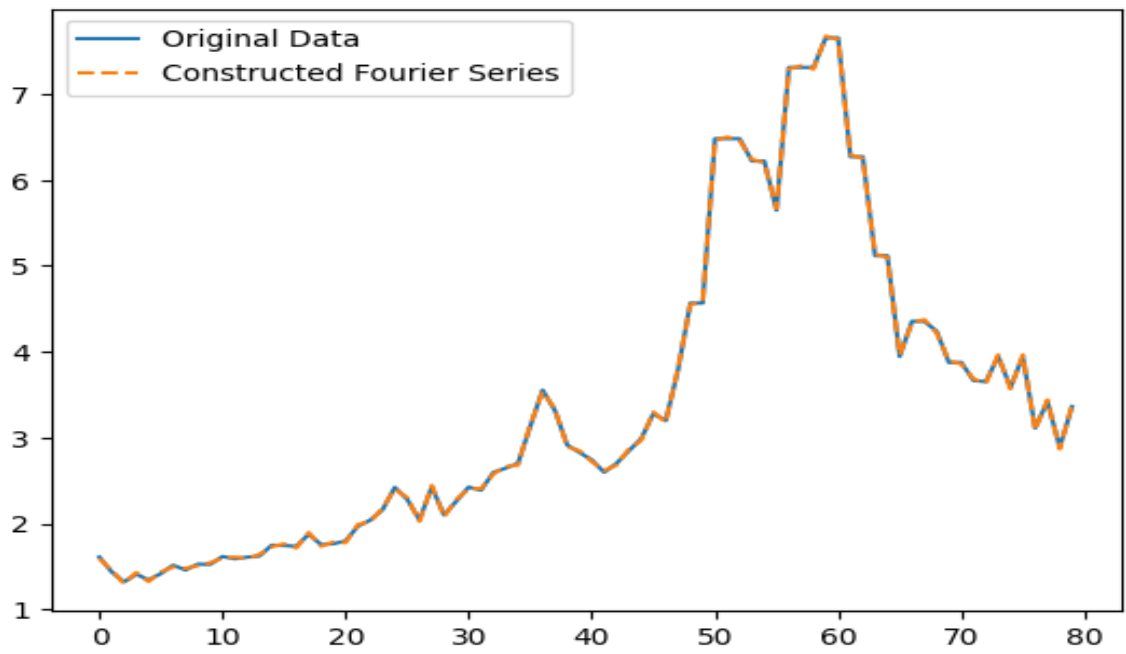

K=1 between 0-25

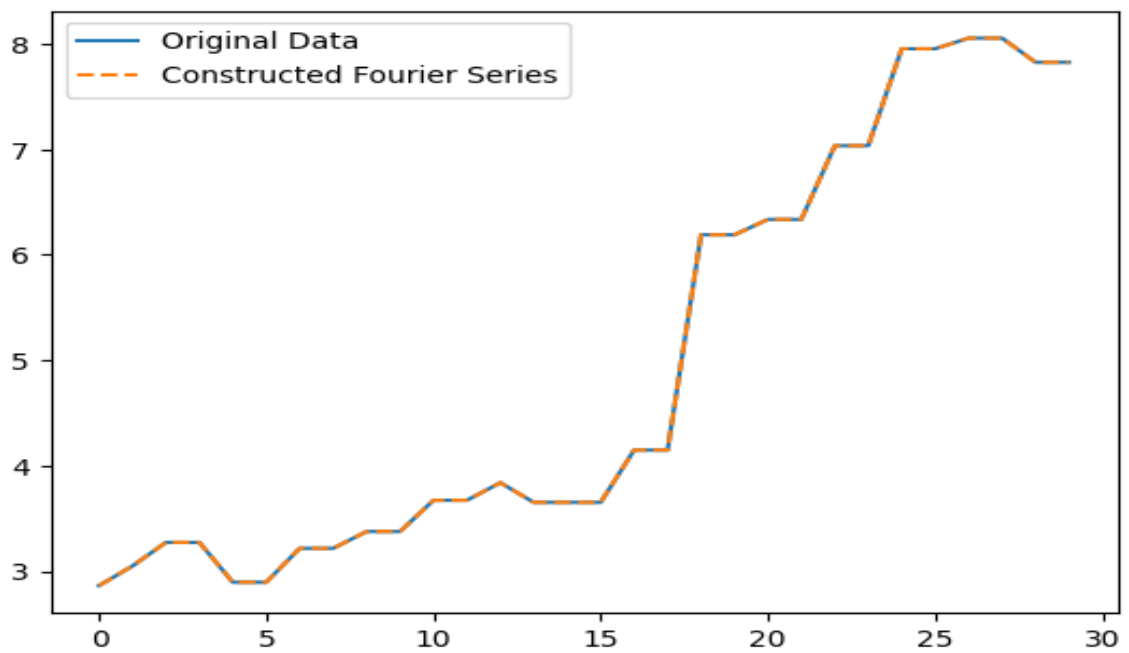

K=2 between 25-140

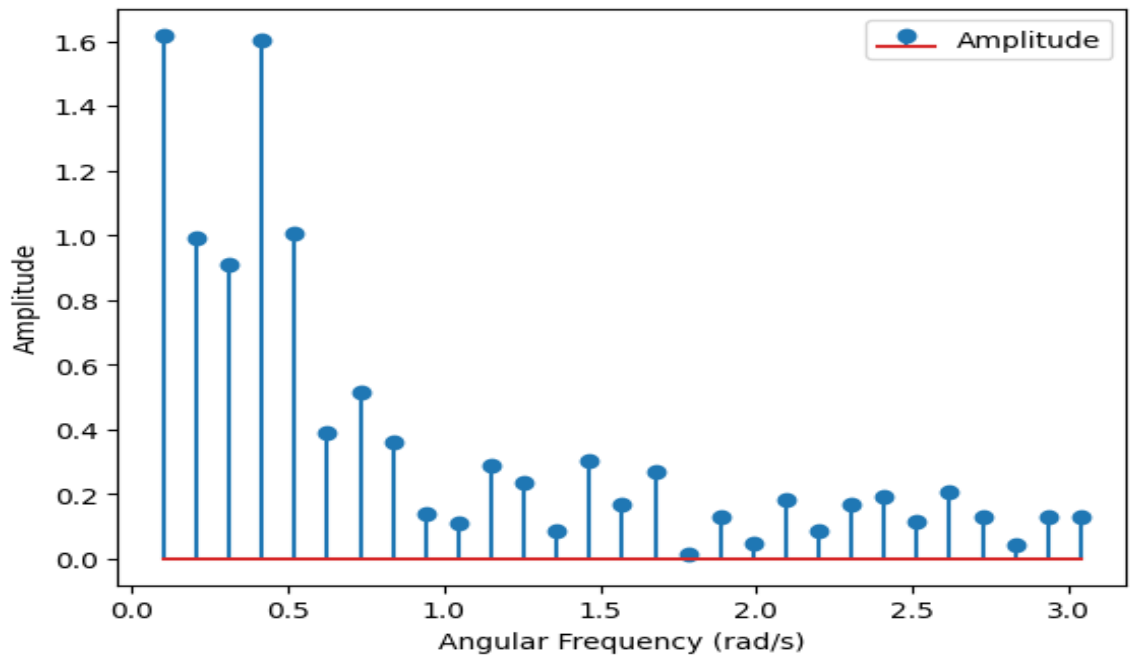

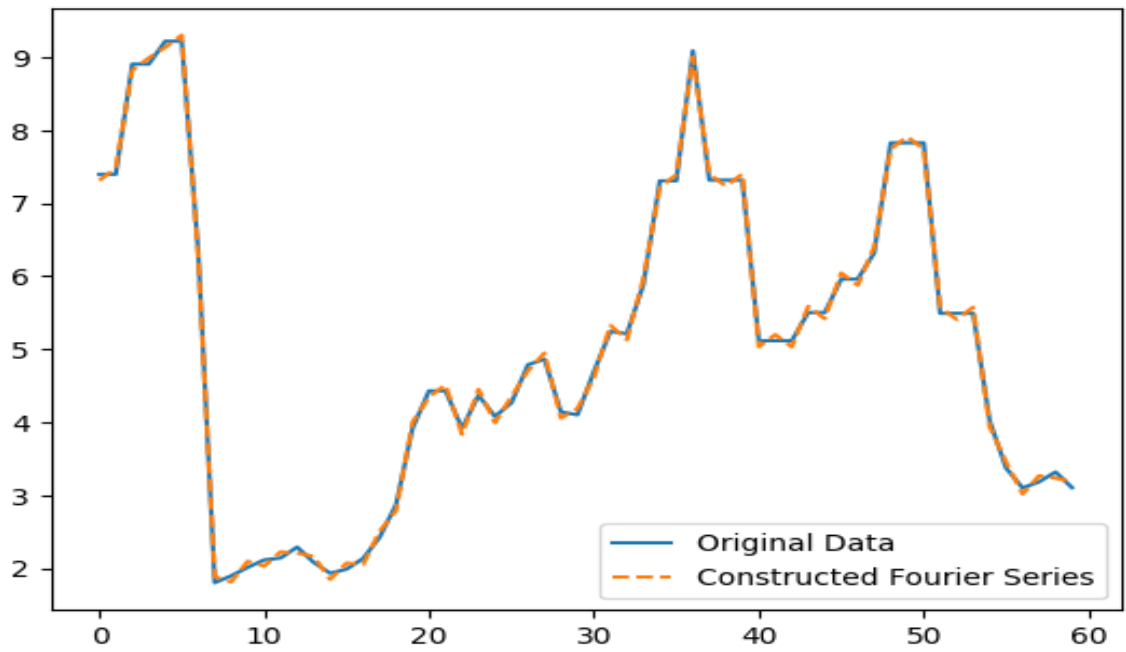

K=3 between 140-220

K=4 between 220-250

K=5 between 250-310

K=6 between 310-350

K=7 between 350-506

Overall series (0 -506)
